The southwest monsoon is of prime importance for the Indian sub-continent as it contributes the majority of annual rainfall. Any major departure from normal monsoon behavior seriously affects agricultural yield and the economy. To enable successful monsoon forecasting in order to plan agricultural activities, a systematic study of variations in monsoonal rainfall is required. This calls for long-term records of past rainfall. In tropical India, the major growth of speleothems occurs during the southwest monsoon (June to September) when water is most abundant. Therefore, speleothems would seem to show good potential as a rainfall proxy.

While \( \delta^{18}O \) of tropical precipitation shows an inverse correlation with the amount of rainfall, it does not show a correlation with surface air temperature (Dansgaard, 1964). Speleothem \( \delta^{18}O \), on the other hand, is related to both the \( \delta^{18}O \) of meteoric water and the temperature of the cave during carbonate precipitation. Therefore, it should in principle function as a proxy for past variations in the \( \delta^{18}O \) of meteoric water and the mean annual surface air temperature. Such an argument can be tested using a young speleothem.

An active stalagmite (Fig. 1), with distinct annual layers covering the past 331 years (the tip is AD 1996), was found in the Akalagavi cave in the mountainous terrain of the Western Ghats, in the state of Karnataka, peninsular India (Yadava et al., submitted). \( \delta^{18}O \) measured along the growth axis varies between -2.7 and +1.6\% (Fig. 2). During the past 300 years, mean annual temperature fluctuations of more than 1°C (corresponding to only a ~0.22% change in the speleothem \( \delta^{18}O \)) seem unlikely. Hence, past \( \delta^{18}O \) variations in precipitation may have been largely responsible for the variations observed in speleothem \( \delta^{18}O \).

If speleothem \( \delta^{18}O \) is primarily governed by variation in rainfall, then a comparison of the \( \delta^{18}O \) time series of the most recent part of the speleothem with the instrumental rainfall record of the region should result in a high correlation coefficient. Indeed, a comparison of the decadal running mean yields a significant value \( (r = -0.62, n = 80) \). This suggests that \( \delta^{18}O \) in cave deposits is a reasonable proxy for decadal variations in local rainfall. A strong positive correlation \( (r = 0.62, n = 301) \) between \( \delta^{18}O \) and \( \delta^{13}C \) along the growth axis indicates that on an annual scale, \( \delta^{13}C \) is also correlated with rainfall.

Reconstruction of Rainfall at the Cave Site

IAEA island stations monitoring \( \delta^{18}O \) in precipitation located in the equatorial belt, where annual temperature fluctuations remain within a narrow range, record a negative correlation between mean monthly \( \delta^{18}O \) of precipitation and mean monthly rainfall (Yurtsever and Gat, 1981). The average rate of depletion is found to be -1.5% per 100 mm increase in monthly rainfall. This depletion rate should also be applicable to the coastal site where Akalagavi cave is located, since annual temperature fluctuations remain within a narrow range. At one of the sites influenced by the southwest monsoon, direct sampling of precipitation samples shows a similar depletion rate (-2.2 ± 0.8% per 100mm). Fig. 2 shows the \( \delta^{18}O \) of the Akalagavi stalagmite converted into rainfall. Assumptions made include that changes in the speleothem \( \delta^{18}O \) were solely due to variations in the amount-dependent \( \delta^{18}O \) of the annual rain and that the depletion rate observed at the island stations is also applicable to the vapor sources at the cave site.

Period Covered by Instrumental Data (after AD 1813)

Years in which rainfall at a site is greater than the long-term average rainfall by more than 10% are defined as “excess” rainfall years (ER). Years in which it is lower by 10% or more are defined as “deficient” rainfall years (DR). Some of the severely deficient rainfall years (1982, 1979, 1941, 1925, 1918, 1915, 1905, 1899, 1877, 1854, 1815) as well as most of the excess rainfall years (e.g. 1988, 1975, 1961, 1956, 1953, 1917, 1910, 1894, 1893, 1884, 1878) observed in the AISRTS (All India Summer Rainfall Time Series) are also recorded in our speleothem-based rainfall reconstruction. Differences in timing, ranging from 0-6 years, are most likely due to errors in lamination chronology or to genuine differences in local rainfall as compared with the AISRTS.

The instrumental data in the rainfall reconstruction show an increasing trend over coastal and north-interior Karnataka from 1901-75. A dry period between 1901-30 in the AISRTS is clearly recorded as shortened width of layers and enriched level of \( \delta^{18}O \) in the speleothem. Similarly, wet conditions from 1931-60 are also reflected in the speleothem. The dry conditions from 1961-90 are marked in our reconstruction by persistent deficient rainfall conditions. However, only some of the individual deficient rain-
The Potential of Oxygen Isotopes in Diatoms as a Paleoclimate Indicator in Lake Sediments

Oxygen isotope ratios ($\delta^{18}O$) measured in authigenic minerals are a valuable proxy for assessing paleoclimate, recording the ambient water temperature and $\delta^{18}O$ composition of the lake water at the time of formation (see Leng and Marshall, 2004). $\delta^{18}O$ measured from lake carbonates (authigenic carbonate, ostracods, etc.) has become a well-established paleoclimate technique, but in di-late and non-alkaline lakes where carbonates are rare, there are only a few suitable alternatives. The measurement of $\delta^{18}O$ in biogenic silica (mainly diatoms) is being increasingly utilised in low carbonate lakes (e.g. Barker et al., 2001; Shemesh et al., 2001). Diatoms are photosynthetic algae that secrete an internal shell composed of opaline silica ($SiO_2 \cdot H_2O$) and are present in most lake sediments apart from some very alkaline lakes (typically pH > 9), or lakes where silica is limited (Barker et al., 1994). Here we discuss the types of lakes that are most suitable for this technique, the information that can be generated, and the potential problems.

**The Effect of Lake Location on $\delta^{18}O_{diatom}$ Interpretation**

The majority of lakes, for which oxygen isotope ratios from diatom silica...
