The Paleoclimate Reconstruction Challenge

CASPAR AMMANN
National Center for Atmospheric Research, Boulder, USA; ammann@ucar.edu

Detailed understanding of the full range of annual and seasonal climate variability over the past millennium forms an important basis for the interpretation of the observed record, and for gauging the response of the climate system to various forcings. Using different methods and proxy networks, the climate reconstructions available show general similarity in their depiction of large-scale mean-temperature evolution, particularly at the decadal to centennial timescale. There are, however, important differences in reconstructions at the interannual and multi-centennial to millennial scale. It is unclear whether these differences result from the selection of specific proxy networks, the potential inability of the included proxies to resolve information at all timescales, or the algorithms themselves (National Research Council, 2006). The paleoclimate community needs to establish a protocol for reassessing its methods to rebuild confidence in the reconstruction efforts.

The last millennium Paleoclimate Reconstruction (PR) Challenge—run under the auspices of the PAGES-CLIVAR-intersection and co-sponsored by the Electric Power Research Institute (EPRI)—will allow us to directly address these concerns and to establish objective reconstruction benchmarks. The idea is to use results from state-of-the-art coupled Atmosphere-Ocean-General Circulation Models (AOGCMs) in both open- and blind-test reconstruction exercises. Individual reconstruction groups (and anyone who would like to participate) will be brought together and issued a small set of realistic pseudo-proxy series and calibrated “instrumental data” drawn from the model output. They will be asked to reconstruct the simulated climate evolution to the best of their technique’s ability. By comparing reconstructions with the full, “true” model climates, each group can assess their performance in great detail. A key objective of this project is to document how much of the true climate can be described with the combined set of reconstruction results, to determine which aspects of the overall or regional climate are captured well, and whether important elements are being missed.

Beyond the main goal of improved understanding of the performance of climate reconstruction methods, it is hoped that the PR Challenge will improve exchange among the different paleoclimate reconstruction groups and provide a flexible platform for enhanced interaction with the associated disciplines in climate modeling and statistics. The latter might be particularly helpful with regard to a more formal assessment and quantification of uncertainty and regional climate understanding. The results of the PR Challenge will support and steer the community to develop strategies for improving reconstruction methods, so that past climate variations can be better understood.
